QA–LOAD RUNNER–BASIC

Load Runner is a performance and load testing product for examining system behaviour and performance, while generating actual load. Load Runner can emulate hundreds or thousands of concurrent users to put the application through the rigors of real-life user loads, while collecting information from key infrastructure components (Web servers, database servers etc). The results can then be analyzed in detail, to explore the reasons for particular behaviour.

In this course at IIBS student will learn about the basics of this course. Like Identify information for load testing, Identify the components of load runner, Performance Monitors, etc.
